# A New Description of Nuclear Rotational Motion in terms of Intrinsic Pair Mode

Daisuke Hayashi, Makoto Ueno*), and Yoshinao Miyanishi

*Graduate School of Science, Nagoya University, Nagoya 464-8602*

(Received )

A new method describing nuclear rotational motion microscopically is proposed. We extract the rotational Hamiltonian by introducing the intrinsic pair modes which commute with the rotational mode. Thereby the rotational mode is not treated as zero energy mode in contrast with the conventional RPA formalism so that we circumvent the difficulty related with infrared divergence. The wave function is constructed by angular momentum projection on each intrinsic state. Without numerical integration for projection we calculate the matrix elements analytically under a certain approximation. The numerical calculations are carried out to illustrate the applicability of our method and they show that our method works well.

## §1. Introduction

The study of rotating nuclei is one of the main topics of the nuclear physics. In order to describe nuclear rotational motion microscopically, *the mean field approximation* is often used, such as *the cranked-Hartree-Fock-Bogoliubov* (CHFB) *theory*1). Although this approach succeeded in explaining the various phenomena of rotating nuclei, it has a serious defect; the method inevitably accompanies *the spontaneous symmetry breaking* and thus the angular momentum is conserved only on the average. The resultant wave functions are no more the eigenstates of angular momentum.

Many works toward the restoration of broken symmetry have been made. One of the useful approaches is *the projection method*2) - 6), that is *the angular momentum projection* (AMP) in this case. AMP is a mathematically rigorous method. However it needs much of a numerical effort. Furthermore the conventional treatment of AMP loses the simple picture of intrinsic excitation. Therefore the projection method has been applied in approximate version 7) 8). Owing to the recent development of computer technology, the calculations with full projection, that is *the projected shell model* (PSM) *calculations* (for a review, see Ref. 9), has been carried out although they are still limited. The application to axially deformed nuclei are carried out 10) - 14). Furthermore the calculation including triaxiality have been made 15) - 17) in transitional region. In these works *the Nilsson-plus-BCS state* is adopted as the intrinsic wave function, that means the self-consistent treatment of the coupling between the rotational mode and intrinsic mode is not fully considered. The application to the CHFB state, in which the axial symmetry is no more kept, is also made 18) - 20), but the effect of the intrinsic excitation is not took into account.

*The random-phase approximation* (RPA) is another useful approach. This method separates the rotational mode as zero-energy mode from the intrinsic mode and restores the broken symmetry within its approximation. However this method also has a shortcoming 21); it is valid for only the small amplitude oscillation, while the zero energy mode ranges over the large amplitude because of no restoring force. This discrepancy, for example, appears as the divergence of the norm of RPA ground state. Although the attempts to overcome this difficulty have been made, the description of finite rotation starting from the small amplitude approximation has its own difficulty 21) - 23).

*) Present address, FUJISOFT ABC Inc. 6-26 Nishiki 1-chome, Naka-ku, Nagoya-shi, Aichi 460-0003, Japan.

In this work we propose a new method to get rid of the difficulty of RPA and to give an approximate treatment for AMP at the same time. The essential point is that we do not treat the angular momentum as an eigenmode although the intrinsic mode is decoupled with it. The wave function having the definite angular momentum is formally given by the angular momentum projection. However we give an analytic expression for the matrix elements between these states without integration. For simplicity, in the present work, the nucleus is assumed to be axially deformed.

In §2, the outline of our method is shown together with a brief review of RPA. §3 is devoted to the formulation of our method in which the rotational Hamiltonian is extracted by introducing the intrinsic operator. The wave functions are obtained in the subspace spanned by the multi-intrinsic pair base. In §4, we derive the analytic expression for the moment of inertia and $B(E2)$ transition probability under a certain approximation. The numerical calculation is made to check the validity of our method and the results are compared with those of RPA and AMP in §5. Finally the summary is given in §6.

## §2. Basic Idea

We begin this section with a brief review of RPA. In axially symmetric system, $\hat{J}_z$ has the good quantum number. The RPA vibrational phonon operators $\mathcal{O}_n^\dagger, \mathcal{O}_n$ are derived from the equation

$$\left[\hat{H}, \mathcal{O}_n^\dagger\right]_{RPA} = E_n \mathcal{O}_n^\dagger. \tag{2·1}$$

The subscription $RPA$ denotes that the only leading terms are considered. In the solution of this equation, however, the zero energy mode $\hat{J}_\pm$ appears

$$\left[\hat{H}, \hat{J}_\pm\right]_{RPA} = 0, \tag{2·2}$$

where $\hat{J}_\pm = \hat{J}_x \pm i\hat{J}_y$. Eq.(2·2) means that the symmetry broken by the mean field approximation is restored. $\hat{H}_{RPA}$ is completely divided into the rotational part and vibrational part within its approximation.

$$\hat{H}_{RPA} = E_{RPA} + \frac{\hat{J}_- \hat{J}_+}{2\mathcal{J}_0} + \sum_n E_n \mathcal{O}_n^\dagger \mathcal{O}_n, \tag{2·3}$$

where $E_{RPA} = \langle 0_{RPA} | \hat{H} | 0_{RPA} \rangle$ and $| 0_{RPA} \rangle$ is RPA vacuum defined by

$$\mathcal{O}_n | 0_{RPA} \rangle = 0, \tag{2·4}$$

$$\hat{J}_\pm | 0_{RPA} \rangle = 0. \tag{2·5}$$

However this definition leads to the well-known difficulty; the norm $\langle 0_{RPA}|0_{RPA}\rangle$ diverges infinitely. It stems from the fact the rotational mode is treated as an eigenmode.

Our approach is proposed in order to avoid this difficulty. We also separate the rotational mode and intrinsic mode but we never treat the rotational mode as an eigenmode. For the first step, the intrinsic pair operator $X_n^\dagger$ is defined as the commutable mode with $\hat{J}_\pm$ in lowest order,

$$\left[\hat{J}_\pm, X_n^\dagger\right] = 0. \tag{2·6}$$

The second step is to represent the Hamiltonian in terms of $\hat{J}_\pm, X_n^\dagger, X_n$ and to decompose it to three parts,

$$\hat{H} = \hat{H}_{rot} + \hat{H}_{intr} + \hat{H}_{coupl} + (\text{const.}), \tag{2·7}$$

where

$$\hat{H}_{rot} = \hat{H}_{rot}(\hat{J}_-\hat{J}_+), \tag{2·8}$$
$$\hat{H}_{intr} = \hat{H}_{intr}(X_n^\dagger, X_n), \tag{2·9}$$
$$\hat{H}_{coupl} = \hat{H}_{coupl}(\hat{J}_\pm, X_n^\dagger, X_n). \tag{2·10}$$

For the last step, $\hat{H}$ is diagonalized in the subspace spanned by *the projected multi-intrinsic pair base*

$$\{|IM\,\rangle\} = \{\hat{P}^I_{M0}\,|0\,\rangle\,, \hat{P}^I_{MK}X_n^\dagger\,|0\,\rangle\,, \hat{P}^I_{MK}X_n^\dagger X_{n'}^\dagger\,|0\,\rangle\,, ...\}, \tag{2·11}$$

where $\hat{P}^I_{MK}$ is the angular momentum projection operator.

In the usual projection method like PSM, $\hat{H}$ is diagonalized in *the projected Tamm-Dancoff base*

$$\{|IM\,\rangle\} = \{\hat{P}^I_{M0}\,|0\,\rangle\,, \hat{P}^I_{MK}\left(a^\dagger a^\dagger\right)_\pi |0\,\rangle\,, \hat{P}^I_{MK}\left(a^\dagger a^\dagger\right)_\nu |0\,\rangle\,, ...\}. \tag{2·12}$$

It should be noted that $(a^\dagger a^\dagger)_\pi, (a^\dagger a^\dagger)_\nu$ include both the rotational and intrinsic modes, while the rotational mode is already eliminated in $X_n^\dagger$ in lowest order. This leads to an advantage of our approach that the analytic form of matrix is approximately obtained without integral calculation. (See §3.)

## §3. Formulation

### 3.1. *Intrinsic Pair Operator*

In axially symmetric system, any operator is classified by $K$ quantum number. In this case, $\hat{J}_\pm$ corresponds to the rotational mode. It is written in the quasi-particle representation as

$$\hat{J}_\pm = \sum_{\alpha<\beta}\left\{J^{20}_{\pm\,\alpha\beta}a^\dagger_\alpha a^\dagger_\beta + J^{02}_{\pm\,\alpha\beta}a_\beta a_\alpha\right\} + \sum_{\alpha\beta}J^{11}_{\pm\,\alpha\beta}a^\dagger_\alpha a_\beta, \tag{3·1}$$

where we follow the notation of Ref. 1). The collective pair operator $X^\dagger_\pm$ is defined as

$$X^\dagger_\pm \equiv \sum_{\alpha<\beta} \psi^{(\pm)}_{\alpha\beta} a^\dagger_\alpha a^\dagger_\beta, \tag{3·2}$$

$$\hat{J}_\pm = a_0 \left( X^\dagger_\pm + X_\mp \right) + \sum_{\alpha\beta} J^{11}_{\pm\,\alpha\beta} a^\dagger_\alpha a_\beta, \tag{3·3}$$

where $a_0 = \langle 0 \,| \hat{J}_- \hat{J}_+ \,| 0 \rangle^{1/2}$. Since $a_0$ is large enough in deformed nuclei

$$\hat{J}_\pm \simeq a_0 \left( X^\dagger_\pm + X_\mp \right) \tag{3·4}$$

The intrinsic pair operator is defined so as it may satisfy (2·6) up to the leading order, that means

$$X^\dagger_n \equiv \sum_{\alpha<\beta} \psi^{(n)}_{\alpha\beta} a^\dagger_\alpha a^\dagger_\beta \tag{3·5}$$

$$\sum_{\alpha<\beta} \psi^{(\pm)*}_{\alpha\beta} \psi^{(n)}_{\alpha\beta} = 0. \tag{3·6}$$

From now on, we use the following notation rule; the subscription '±' or '$c$' denotes the collective mode and '$n$' denotes the intrinsic one and '$\mu, \nu, ...$' denotes both. If necessary, $K$ quantum number subscription is added, as *e.g.* $X^\dagger_{nK}$. The amplitudes $\psi^{(\mu)}_{\alpha\beta}$ satisfy the orthogonality and completeness

$$\sum_{\alpha<\beta} \psi^{(\mu)*}_{\alpha\beta} \psi^{(\nu)}_{\alpha\beta} = \delta_{\mu\nu}, \tag{3·7}$$

$$\sum_{\mu} \psi^{(\mu)*}_{\alpha\beta} \psi^{(\nu)}_{\alpha'\beta'} = \delta_{\alpha\alpha'} \delta_{\beta\beta'} \qquad (\alpha < \beta). \tag{3·8}$$

They can be simultaneously determined from the eigenvalue equation for the Stability matrix

$$\sum_{\alpha<\beta} \sum_{\alpha'<\beta'} \psi^{(\mu)*}_{\alpha\beta} (\mathcal{A}_{\alpha\beta;\alpha'\beta'} + \mathcal{B}_{\alpha\beta;\overline{\alpha'\beta'}}) \psi^{(\nu)}_{\alpha'\beta'} = \omega_\mu \delta_{\mu\nu}, \tag{3·9}$$

where

$$\mathcal{A}_{\alpha\beta;\alpha'\beta'} = \langle 0 \,| [a_\beta a_\alpha, [\hat{H}, a^\dagger_{\alpha'} a^\dagger_{\beta'}]] \,| 0 \rangle, \tag{3·10}$$

$$\mathcal{B}_{\alpha\beta;\alpha'\beta'} = -\langle 0 \,| [a_\beta a_\alpha, [\hat{H}, a_{\alpha'} a_{\beta'}]] \,| 0 \rangle, \tag{3·11}$$

and $\overline{\alpha'\beta'}$ denotes the time-reversal index of $\alpha'\beta'$.

### 3.2. *Extraction of the rotational Hamiltonian*

The Hamiltonian with two-body interaction is written in terms of pair operators up to leading order (Appendix A),

$$\hat{H} \simeq \langle H \rangle + \sum_n \omega_n X^\dagger_n X_n + \sum_{\mu\nu} \left[ V_{v(\mu\bar{\nu})} \left( X^\dagger_\mu X^\dagger_{\bar{\nu}} + X_{\bar{\nu}} X_\mu + 2 X^\dagger_\mu X_\nu \right) \right], \tag{3·12}$$

where $V_{v(\mu\nu)}$ is a newly defined matrix

$$V_{v(\mu\nu)}=\sum_{\alpha\beta}\sum_{\alpha'\beta'}\psi^{(\mu)*}_{\alpha\beta}H^{40}_{\alpha\beta;\alpha'\beta'}\psi^{(\nu)*}_{\alpha'\beta'}. \tag{3·13}$$

By classifying (3·12) with respect to each mode, $\hat{H}$ can be decomposed into the rotational part $\hat{H}_{rot}$ which can be written only by the collective pairs, the intrinsic part $\hat{H}_{intr}$ only by the intrinsic pairs, and their coupling part $\hat{H}_{coupl}$

$$\hat{H}_{rot}=\frac{2V_{v(+-)}}{a_0^2}\hat{J}_-\hat{J}_+, \tag{3·14}$$

$$\hat{H}_{intr}=\sum_n\omega_nX^\dagger_nX_n+\sum_{n,n'}V_{v(n\bar{n}')}\left(X^\dagger_nX^\dagger_{\bar{n}'}+X_{\bar{n}'}X_n+2X^\dagger_nX_{n'}\right), \tag{3·15}$$

$$\hat{H}_{coupl}=2\sum_{n,c}V_{v(n\bar{c})}\left(X^\dagger_nX^\dagger_{\bar{c}}+X_{\bar{c}}X_n+X^\dagger_nX_c+X^\dagger_{\bar{c}}X_{\bar{n}}\right). \tag{3·16}$$

In Eq.(3·14) we used (3·4).

### 3.3. *Wave function*

We span the intrinsic space

$$|k_l\rangle=X^\dagger_{n_1}...X^\dagger_{n_l}|0\rangle, \tag{3·17}$$

and make the wave function in the following base

$$\{|IM\rangle\}=\{\hat{P}^I_{MK}|k_l\rangle\} \tag{3·18}$$

where

$$\hat{P}^I_{MK}=\frac{2I+1}{8\pi^2}\int_0^{2\pi}d\alpha\int_0^{\pi}d\beta sin\beta\int_0^{2\pi}d\gamma D^{I^*}_{MK}(\alpha,\beta,\gamma)e^{-i\alpha\hat{J}_z}e^{-i\beta\hat{J}_y}e^{-i\gamma\hat{J}_z}. \tag{3·19}$$

Because $\hat{J}_\pm$ change into c-numbers when they are operated to these states, all we have to do is calculate the norm matrix of this base.

Here we note that $K\geq 0$ intrinsic pairs have to be prepared to compose the orthogonal base because

$$\begin{aligned}\langle 0|X_{nK}P^I_{KK}X^\dagger_{nK}|0\rangle&=\langle 0|X_{n-K}P^I_{-KK}X^\dagger_{nK}|0\rangle\\&=\langle 0|X_{n-K}P^I_{-K-K}X^\dagger_{n-K}|0\rangle.\end{aligned} \tag{3·20}$$

This property stems from the time-reversal symmetry of the HFB wave function in the axially deformed system. Moreover, through this study, we neglect the non-diagonal elements of the norm matrix

$$\langle 0|\hat{P}^I_{0K}X^\dagger_{n_K}|0\rangle,\quad\langle 0|\hat{P}^I_{MK}X^\dagger_nX^\dagger_{n'}|0\rangle,\quad\langle 0|X_n\hat{P}^I_{MK}X^\dagger_{n'}X^\dagger_{n''}|0\rangle,... \tag{3·21}$$

compared with $\langle 0|\hat{P}^I_{00}|0\rangle$. This is because $\hat{P}^I_{MK}$ includes only the rotational mode which is orthogonal to the intrinsic mode in lowest order. Under this approximation, we can calculate the matrix without integration.

## §4. Physical Quantities

### 4.1. *Moment of Inertia*

#### 4.1.1. Peierls-Yoccoz' Moment of Inertia

*The Peierls-Yoccoz' moment of inertia*[25)] is defined

$$\begin{aligned} E_I &= \langle IM\,|\hat{H}\,|IM\,\rangle \\ &= E_0 + \frac{I(I+1)}{2\mathcal{J}_{PY}}, \end{aligned} \tag{4·1}$$

where $|IM\,\rangle$ is determined as following

$$|IM\,\rangle = \mathcal{N}_0^I \hat{P}^I_{M0}\,|0\,\rangle \tag{4·2}$$

where the normalization constant $\mathcal{N}_0^I = \langle 0\,|P^I_{00}\,|0\,\rangle^{-1/2}$. Comparing (4·1) with (3·14) − (3·16) under the approximation mentioned above, the Peierls-Yoccoz' moment of inertia can be derived analytically

$$\mathcal{J}_{PY} = \frac{a_0^2}{4Vv_{(+-)}}. \tag{4·3}$$

#### 4.1.2. Thouless-Valatin Moment of Inertia

As a rule *the Peierls-Yoccoz' moment of inertia* tends to underestimate the experimental value[24)], and thus we extend the physical space by adding $K = 1$ one phonon states perturbatively

$$|IM\,\rangle \simeq \mathcal{N}_0^I \hat{P}^I_{M0}\,|0\,\rangle + \eta \sum_{n_{K=+1}} \mathcal{N}^I_{n_{+1}} \hat{P}^I_{M1} X^\dagger_{n_{+1}}\,|0\,\rangle\,, \tag{4·4}$$

where

$$\mathcal{N}^I_{n_K} = \langle 0\,|X_{n_K} \hat{P}^I_{KK} X^\dagger_{n_K}\,|0\,\rangle^{-1/2}.$$

The perturbative energy shift in second order is given by

$$\mathit{\Delta} E = -\sum_{n_{K=+1}} \frac{|\mathcal{N}_0^I \mathcal{N}^I_{n_{+1}} \langle 0\,|\hat{P}^I_{0M} \hat{H} \hat{P}^I_{M1} X^\dagger_{n_{+1}}\,|0\,\rangle|^2}{\omega_n}. \tag{4·5}$$

Here we must mention that the definitions of $\omega_n$ and $X^\dagger_{n_K}$ are slightly different from those of (3·9) because the formers are defined as the Tamm-Dancoff eigenvalues and eigenvectors in the intrinsic space, i.e. they are derived by diagonalization of $\mathcal{A}$ after removing the zero energy modes.

In addition to (3·21), we also neglect the terms

$$\langle 0\,|X_{n_{+1}} \hat{P}^I_{11} X^\dagger_{n'_{+1}}\,|0\,\rangle. \qquad (n \neq n') \tag{4·6}$$

compared with $\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle$. $\mathit{\Delta} E$ can be derived analytically

$$\mathit{\Delta} E \simeq -8I(I+1)a_0^{-2} \sum_{n_{K=+1}} \omega_n^{-1} V_v^2(n_{+1}\,-). \tag{4·7}$$

Here we used the approximate relation (see Appendix B),

$$\frac{\langle 0\,|X_{n_{+1}}\hat{P}^I_{11}X^{\dagger}_{n_{+1}}\,|0\,\rangle}{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle} \simeq \frac{V_v(+\;n_{-1})}{2V_v(n_{+1}\;-)} = \frac{1}{2}. \tag{4·8}$$

which can be naturally derived from our approximation. Thereby the moment of inertia is newly defined

$$\frac{I(I+1)}{2\mathcal{J}_{PY}} + \varDelta E = \frac{I(I+1)}{2\mathcal{J}_{eff}}. \tag{4·9}$$

where $\mathcal{J}_{eff}$ corresponds to *the Thouless-Valatin moment of inertia* $\mathcal{J}_{TV}$, which coincides with $\mathcal{J}_0$ in (2·3). It is calculated from

$$\mathcal{J}_0 = 2\sum_{\alpha\beta;\alpha'\beta'} \psi^{(c)*}_{\alpha\beta}(\mathcal{A}-\mathcal{B})^{-1}_{\alpha\beta;\alpha'\beta'}\psi^{(c)}_{\alpha'\beta'}. \tag{4·10}$$

### 4.2. *B(E2) Transition Probability*

The $B(E2)$ transition probability in the ground band also derived in the same framework. In the space $|IM\,\rangle = \mathcal{N}_0\hat{P}^I_{M0}\,|0\,\rangle$, it can be written

$$B(E2; I+2 \rightarrow I) = \left[\frac{\mathcal{N}_0^{I+2}}{\mathcal{N}_0^I}\sum_{\lambda=-2}^{2}\langle I\;-\lambda; 2\,\lambda\,|I+2\,0\,\rangle\; g_\lambda(I)\right]^2, \tag{4·11}$$

where $g_\lambda(I)$ is given by

$$g_\lambda(I) \equiv (-1)^\lambda\frac{\langle 0\,|\hat{P}^I_{0\lambda}\hat{Q}_{2\lambda}\,|0\,\rangle}{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle}. \tag{4·12}$$

$g_\lambda(I)$ and $\mathcal{N}_0^{I+2}/\mathcal{N}_0^I$ can be given the analytic form in our approximation. (See Appendix C.)

$$g_\lambda(I) \simeq \begin{cases} \left\langle \hat{Q}_{20}\right\rangle & (\text{for} \quad \lambda = 0) \\ -\xi_{\pm}a_0^{-1}\sqrt{I(I+1)} & (\text{for} \quad \lambda = \pm 1) \\ 0 & (\text{for} \quad \lambda = \pm 2) \end{cases} . \tag{4·13}$$

Here $\xi_\mu$ is the overlap coefficient

$$\xi_{\mu_K} = \langle 0\,|X_{\mu_K}\hat{Q}_{2K}\,|0\,\rangle \tag{4·14}$$

and

$$\left(\frac{\mathcal{N}_0^{I+2}}{\mathcal{N}_0^I}\right)^2 = \frac{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle}{\langle 0\,|\hat{P}^{I+2}_{00}\,|0\,\rangle} = \sqrt{\frac{2I+1}{2I+5}}\;\;\frac{\sum_\lambda\langle I{+}2\;\lambda; 2\;-\lambda\,|I0\,\rangle\; g_{\lambda(I+2)}}{\sum_\lambda\langle I\;\lambda; 2\;-\lambda\,|I{+}2\;0\,\rangle\; g_{\lambda(I)}}. \tag{4·15}$$

From (4·15) and the normalization condition $\sum_I\langle 0\,|\hat{P}^I\,|0\,\rangle = 1$, the angular momentum distributions of the HFB wave function $|0\,\rangle$ can be analytically evaluated.

## §5. Numerical Calculation

We carry out the numerical calculation applying our method to Er isotopes and compare the results with AMP and RPA. As the purpose is to check the validity of our method, we adopt a rather simple effective interaction; *the Pairing-plus-Quadrupole interaction*. The detail correspondence with experimental data by using the more realistic interaction is left in the future study.

The adopted Hamiltonian is

$$\hat{H} = \hat{H}_0 - \frac{1}{2}\chi \sum_{\lambda=-2}^{2} \hat{Q}^{\dagger}_{2\lambda}\hat{Q}_{2\lambda} - G\hat{P}^{\dagger}\hat{P}, \tag{5·1}$$

where the chemical potentials are already absorbed in the spherical single particle energy part $\hat{H}_0$. The single particle basis employed is $N = 4$,5 and 6 for neutrons (64 levels) and $N = 3$,4 and 5 for protons (46 levels). The exchange terms are neglected. The force parameters are below; for the *Q-Q interaction*

$$\chi_{nn} = 3.768 \times 10^{-2} \quad \text{(MeV)}, \tag{5·2}$$

$$\chi_{pp} = 4.796 \times 10^{-2} \quad \text{(MeV)}, \tag{5·3}$$

$$\chi_{np} = \chi_{pn} = \sqrt{\chi_{nn}\chi_{pp}} \quad , \tag{5·4}$$

where $\hat{Q}$ is scaled to be dimensionless by the oscillator length $b_0 = \sqrt{\frac{\hbar}{m\omega_0}}$. For *the pairing interaction* we use

$$G = (22.36 \mp 14.59\frac{N-Z}{A})/A \quad \text{(MeV)}, \tag{5·5}$$

where - for neutron and + for proton.

In table I and II, the calculated results for the moment of inertia $\mathcal{J}_{PY}, \mathcal{J}_{T.V.}$ are shown. They indicate that our method gives a good approximation for AMP and RPA.

Table I. Comparison of $\mathcal{J}_{P.Y.}(\hbar^2 \cdot \text{MeV}^{-1})$ obtained from AMP with the one from our method

| | $^{162}$Er | $^{164}$Er | $^{166}$Er | $^{168}$Er |
|---|---|---|---|---|
| AMP | 20.6 | 22.7 | 24.5 | 26.8 |
| ours | 22.4 | 24.5 | 26.1 | 28.6 |

Table II. Comparison of $\mathcal{J}_{T.V.}(\hbar^2 \cdot \text{MeV}^{-1})$ obtained from RPA with the one from our method

| | $^{162}$Er | $^{164}$Er | $^{166}$Er | $^{168}$Er |
|---|---|---|---|---|
| RPA | 29.8 | 33.1 | 35.0 | 38.0 |
| ours | 31.3 | 34.9 | 36.8 | 39.8 |

The small discrepancies among them are supposed to be the consequence of our approximation (3·21). In order to check the accuracy of the diagonal element $\langle 0\,| X_{n+1} \hat{P}^I_{11} X^{\dagger}_{n+1}\,|0\,\rangle / \langle 0\,|\hat{P}^I_{00}\,|0\,\rangle$ (4·8), we calculated it by the exact AMP. The results are shown in Table III. Here we showed the data for the lowest energy intrinsic mode. (We checked the results for the other mode are nearly same.)

The $B(E2)$ transition probability and the angular momentum distributions $\langle 0\,|\hat{P}^I\,|0\,\rangle$ for $^{166}$Er are shown in Table IV and Fig.1. In this calculation, we used the isoscalar effective charge $e_{eff} = 0.3e$. Our method can well reproduce the result of AMP. To look into the origin of good agreements, we calculated $g_\lambda(I)$ by the exact AMP. The results are given in Table V. We find that the main part of $B(E2)$ comes from $g_{\lambda=0}(I)$, which does not depend on the detail of the projection because it is mainly determined by $< Q_{20} >$. The same reason holds for the good agreement of $\langle 0\,|P^I_{00}\,|0\,\rangle$ with the exact one.

Table III. Comparison of Eq.(4·8) obtained from AMP with the one from our method

| $I$ | AMP | approx. |
|---|---|---|
| 2 | 0.49184 | 0.5 |
| 4 | 0.49313 | |
| 6 | 0.49515 | |
| 8 | 0.49788 | |
| 10 | 0.50129 | |
| 12 | 0.50536 | |

## §6. Summary

In this work, we proposed a new microscopic method for the description of nuclear rotational motion that avoids the difficulty of RPA. We separate the rotational Hamiltonian by defining the intrinsic mode that commutes with the rotational mode up to leading order. The wave function with definite angular momentum is formally determined through angular momentum projection, though practical integral calculation is replaced by the analytic estimation under a certain approximation. We calculated moment of inertia and $B(E2)$ transition probability in the ground band by using this method, restricting ourselves to axially deformed system. The obtained results shows good agreements with the ones from AMP and RPA.

This method has various advantages as following; (i) It keeps the clear physical picture of RPA treating the rotational and the intrinsic modes separately. (ii) all the necessary calculations are reduced to merely analytic ones and thus it is easier to include much of an intrinsic excitation.

Finally we mention that this work is still preliminary. To compare with experimental data, more realistic interaction should be applied, such as *the pairing-plus-Quadrupole-plus-Quadrupole-pairing interaction, the Gogny interaction.* Moreover, more elaborate formulation that deals with $K$ quantum number mixing has to be made for the study of high spin state. These works are now in progress.

### —— *Phonon Representation of Hamiltonian* ——

The Hamiltonian with two-body interaction can be written in the quasi-particle space

$$\hat{H} = \langle \hat{H} \rangle + \hat{H}^{11} + \frac{1}{2}(\hat{H}^{20} + \text{h.c.}) + \frac{1}{4}\hat{H}^{22} + (\hat{H}^{31} + \text{h.c.}) + (\hat{H}^{40} + \text{h.c.}), \tag{A·1}$$

where

$$\langle \hat{H} \rangle = \langle 0 | \hat{H} | 0 \rangle, \tag{A·2}$$

$$\hat{H}^{11} = \sum_{\alpha} E_\alpha \hat{B}_{\alpha\alpha}, \tag{A·3}$$

$$\hat{H}^{22} = \sum_{\alpha\beta} \sum_{\alpha'\beta'} H^{22}_{\alpha\beta;\alpha'\beta'} a^\dagger_\alpha a^\dagger_\beta a_{\beta'} a_{\alpha'}, \tag{A·4}$$

$$\hat{H}^{40} = \sum_{\alpha\beta} \sum_{\alpha'\beta'} H^{40}_{\alpha\beta;\alpha'\beta'} a^\dagger_\alpha a^\dagger_\beta a^\dagger_{\alpha'} a^\dagger_{\beta'}, \tag{A·5}$$

$$\hat{H}^{31} = \sum_{\alpha\beta}\sum_{\alpha'\beta'} H^{31}_{\alpha\beta;\alpha'\beta'} a^\dagger_\alpha a^\dagger_\beta a^\dagger_{\alpha'} a_{\beta'}, \tag{A·6}$$

and $\hat{H}^{20} = 0$ in the HFB ground state. $E_\alpha$ is the quasi-particle energy and $\hat{B}_{\alpha\beta}$ is the scattering operator defined by

$$\hat{B}_{\alpha\beta} \equiv a^\dagger_\alpha a_\beta, \tag{A·7}$$

Between $\hat{B}_{\alpha\beta}$ and the pair operators, there exist the following commutation relations

$$[X_\mu, X^\dagger_\nu] = \delta_{\nu\mu} + \sum_{\alpha\beta} \mathit{\Gamma}^{(\nu\mu)}_{\alpha\beta} \hat{B}_{\alpha\beta}, \tag{A·8}$$

$$[\hat{B}_{\alpha\beta}, X^\dagger_\mu] = -\sum_{\nu} \mathit{\Gamma}^{(\nu\mu)}_{\alpha\beta} X^\dagger_\nu, \tag{A·9}$$

where

$$\mathit{\Gamma}^{(\mu\nu)}_{\alpha\beta} = \sum_\gamma \psi^{(\mu)*}_{\alpha\gamma} \psi^{(\nu)}_{\gamma\beta} \tag{A·10}$$

is the first order of magnitude with respect to the small parameter $\epsilon \sim \frac{1}{\sqrt{\mathit{\Omega}}}$ ($\mathit{\Omega}$ is the number of states). $\hat{B}_{\alpha\beta}$ can be rewritten

$$\hat{B}_{\alpha\beta} = -\sum_{\mu\nu} \mathit{\Gamma}^{(\mu\nu)}_{\alpha\beta} X^\dagger_\mu X_\nu + O(\epsilon^2) \tag{A·11}$$

since this form satisfies ($A$·9) except for $O(\epsilon^2)$ deviation. Using the newly defined matrices

$$V_{x(\mu\nu)} = \sum_{\alpha\beta}\sum_{\alpha'\beta'} \psi^{(\mu)*}_{\alpha\beta} H^{22}_{\alpha\beta;\alpha'\beta'} \psi^{(\nu)}_{\alpha'\beta'}, \tag{A·12}$$

$$V_{v(\mu\nu)} = \sum_{\alpha\beta}\sum_{\alpha'\beta'} \psi^{(\mu)*}_{\alpha\beta} H^{40}_{\alpha\beta;\alpha'\beta'} \psi^{(\nu)*}_{\alpha'\beta'}, \tag{A·13}$$

$$V_{y(\mu;\alpha'\beta')} = \sum_{\alpha\beta} \psi^{(\mu)*}_{\alpha\beta} H^{31}_{\alpha\beta;\alpha'\beta'}, \tag{A·14}$$

$\hat{H}$ is rewritten as

$$\begin{aligned}\hat{H} &= \langle \hat{H} \rangle \\ &+ \sum_{\mu\nu} \left\{ \left( -\sum_\alpha E_\alpha \mathit{\Gamma}^{(\mu\nu)}_{\alpha\alpha} + \frac{1}{4} V_{x(\mu\nu)} \right) X^\dagger_\mu X_\nu + V_{v(\mu\bar{\nu})} \left( X^\dagger_\mu X^\dagger_{\bar{\nu}} + X_{\bar{\nu}} X_\mu \right) \right\} + O(\epsilon^2),\end{aligned} \tag{A·15}$$

As the Stability Matrix is (without exchange terms)

$$\mathcal{A}_{\alpha\beta;\alpha'\beta'} = (E_\alpha - E_\beta)(\delta_{\alpha\alpha'}\delta_{\beta\beta'} - \delta_{\alpha\beta'}\delta_{\beta\alpha'}) + H^{22}_{\alpha\beta;\alpha'\beta'}, \tag{A·16}$$

$$\mathcal{B}_{\alpha\beta;\alpha'\beta'} = 8H^{40}_{\alpha\beta;\alpha'\beta'}, \tag{A·17}$$

(3·9) can be rewritten

$$-\sum_{\alpha} E_{\alpha} \mathit{\Gamma}^{(\mu\nu)}_{\alpha\alpha} + \frac{1}{4} V_{x(\mu\nu)} - 2V_{v(\mu\bar{\nu})} = \omega_{\mu}\delta_{\mu\nu}. \tag{A·18}$$

From $(A{\cdot}15)(A{\cdot}18)$, the phonon representation of $\hat{H}$ (3·12) is derived.

## Appendix B
### —— *Evaluation of the $\mathit{\Delta} E$* ——

The perturbative energy shift in the second order is

$$\mathit{\Delta} E = -\sum_{n_{K=1}} \frac{|\mathcal{N}^I_0 \mathcal{N}^I_{n+1} \langle 0\,|\hat{P}^I_{0M} \hat{H} \hat{P}^I_{M1} X^{\dagger}_{n+1}\,|0\,\rangle|^2}{\omega_n}. \tag{B·1}$$

From $\left[\hat{H}, \hat{P}^I_{MK}\right] = 0$,

$$\langle 0\,|\hat{P}^I_{0M} \hat{H} \hat{P}^I_{M1} X^{\dagger}_{n+1}\,|0\,\rangle = \langle 0\,|\hat{H} \hat{P}^I_{01} X^{\dagger}_{n+1}\,|0\,\rangle \tag{B·2}$$

$$= \langle 0\,|\hat{P}^I_{0K} \hat{H} X^{\dagger}_{n+1}\,|0\,\rangle. \tag{B·3}$$

Calculating $(B{\cdot}2), (B{\cdot}3)$ separately under our approximation,

$$\begin{aligned}(B{\cdot}2) &\simeq \langle 0\,|\hat{H}_{coupl.} \hat{P}^I_{01} X^{\dagger}_{n+1}\,|0\,\rangle \\ &\simeq 2V_v(n_{+1}\,-)\langle 0\,|X_{n+1} X_- \hat{P}^I_{01} X^{\dagger}_{n+1}\,|0\,\rangle + 2V_v(n_{-1}\,+)\langle 0\,|X_{n_{-1}} X_+ \hat{P}^I_{01} X^{\dagger}_{n+1}\,|0\,\rangle \\ &= \sqrt{I(I+1)}\,4a_0^{-1} V_v(n_{+1}\,-)\langle 0\,|X_{n_{+1}} \hat{P}^I_{11} X^{\dagger}_{n_{+1}}\,|0\,\rangle, \end{aligned} \tag{B·4}$$

$$\begin{aligned}(B{\cdot}3) &\simeq \langle 0\,|\hat{P}^I_{01} \hat{H}_{coupl.} X^{\dagger}_{n+1}\,|0\,\rangle \\ &\simeq \sqrt{I(I+1)}\,2a_0^{-1} V_v(+\,n_{-1})\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle. \end{aligned} \tag{B·5}$$

From $(B{\cdot}4) = (B{\cdot}5)$,

$$\frac{\langle 0\,|X_{n_{+1}} \hat{P}^I_{11} X^{\dagger}_{n_{+1}}\,|0\,\rangle}{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle} \simeq \frac{V_v(+\,n_{-1})}{2V_v(n_{+1}\,-)} = \frac{1}{2}. \tag{B·6}$$

Here we used the relation $V_v(n_{-1}\,+) = V_v(+\,n_{-1}) = V_v(n_{+1}\,-) = V_v(-\,n_{+1})$ . As the result, $\mathit{\Delta} E$ can be given analytically

$$\mathit{\Delta} E \simeq -I(I+1) \sum_{n_{K=1}} \frac{4V_v^2(n_{+1}\,-)}{\omega_n a_0^2} \frac{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle}{\langle 0\,|X_{n_{+1}} \hat{P}^I_{11} X^{\dagger}_{n_{+1}}\,|0\,\rangle} \tag{B·7}$$

$$\simeq -8I(I+1)a_0^{-2} \sum_{n_{K=1}} \omega_n^{-1} V_v^2(n_{+1}\,-). \tag{B·8}$$

## Appendix C

### —— *Evaluation of the $B(E2)$ and $\langle 0\,|\hat{P}^I\,|0\,\rangle$* ——

$B(E2)$ transition probability is given by

$$B(E2; I{+}2 \rightarrow I) \equiv \frac{1}{2I+5} |\langle I{+}2\,\|\hat{Q}_2\,\| I\,\rangle|^2. \tag{C·1}$$

where $\langle I{+}2\,\|\hat{Q}_2\,\|I\,\rangle$ is *the reduced matrix element* derived from *the Wigner-Eckart theorem*,

$$\langle I{+}2\;M{+}\lambda\,|\hat{Q}_{2\lambda}\,|IM\,\rangle = (2I+1)^{-1/2}\;\langle I{+}2\;M{+}\lambda\,;2\;\;-\lambda\,|I\;M\,\rangle\,\langle I{+}2\,\|\hat{Q}_2\,\|I\,\rangle. \tag{C·2}$$

We have only to calculate $\langle I{+}2\;M\,|\hat{Q}_{20}\,|IM\,\rangle$. In the space $|IM\,\rangle = \mathcal{N}_0 \hat{P}^I_{M0}\,|0\,\rangle$

$$\begin{aligned}&\langle I{+}2\;M\,|\hat{Q}_{20}\,|IM\,\rangle\\ &= \frac{\mathcal{N}_0^{I+2}}{\mathcal{N}_0^I}(-1)^M\,\langle IM;20\,|I{+}2\;\;-M\,\rangle \sum_{\lambda=-2}^{2} \langle I{-}\lambda;2\;\lambda\,|I{+}2\;0\,\rangle\, g_\lambda(I),\end{aligned} \tag{C·3}$$

where

$$g_\lambda(I) \equiv (-1)^\lambda \frac{\langle 0\,|\hat{P}^I_{0\lambda}\hat{Q}_{2\lambda}\,|0\,\rangle}{\langle 0\,|\hat{P}^I_{00}\,|0\,\rangle}. \tag{C·4}$$

Here we used the relation

$$\hat{P}^I_{KM}\hat{Q}_{2\lambda} = \sum_{\lambda' I' M' K'} \langle I'M';2\lambda\,|IM\,\rangle\,\langle I'K';2\lambda'\,|IK\,\rangle\,\hat{Q}_{2\lambda'}\hat{P}^{I'}_{K'M'}. \tag{C·5}$$

Finally we can rewrite the $B(E2)$

$$B(E2; I{+}2 \rightarrow I) = \left[\frac{\mathcal{N}_0^{I+2}}{\mathcal{N}_0^I} \sum_\lambda \langle I\;\;-\lambda;2\;\lambda\,|I{+}2\;0\rangle\;\; g_\lambda(I)\right]^2, \tag{C·6}$$

$g_\lambda(I)$ and $\mathcal{N}_0^{I+2}/\mathcal{N}_0^I$ can be derived approximately. Pair operator representation of $\hat{Q}_{2\lambda}\,|0\,\rangle$ is

$$\hat{Q}_{2\lambda}\,|0\,\rangle = \begin{cases} \left(\left\langle \hat{Q}_{20}\right\rangle + \sum_n \xi_n X_n^\dagger\right)|0\,\rangle & (\text{for} \quad \lambda = 0)\\ \left(\xi_\pm X_\pm^\dagger + \sum_n \xi_n X_n^\dagger\right)|0\,\rangle & (\text{for} \quad \lambda = \pm 1)\\ \sum_n \xi_n X_n^\dagger\,|0\,\rangle & (\text{for} \quad \lambda = \pm 2)\end{cases}. \tag{C·7}$$

From our approximation, $g_\lambda(I)$ can be analytically written.

$$g_\lambda(I) \simeq \begin{cases} \left\langle \hat{Q}_{20}\right\rangle & (\text{for} \quad \lambda = 0)\\ -\xi_\pm a_0^{-1}\sqrt{I(I+1)} & (\text{for} \quad \lambda = \pm 1)\\ 0 & (\text{for} \quad \lambda = \pm 2)\end{cases}. \tag{C·8}$$

On the other hand, $\mathcal{N}_0^{I+2}/\mathcal{N}_0^I$ is derived from $\langle 0\,|\hat{P}^{I+2}_{0M}\,\hat{Q}_{20}\,\hat{P}^{I}_{M0}\,|0\,\rangle$

$$\begin{aligned}
&\langle 0\,|\hat{P}^{I+2}_{0M}\,\hat{Q}_{20}\,\hat{P}^{I}_{M0}\,|0\,\rangle \\
&= \langle IM;20\,|I{+}2\;M\,\rangle\,\langle 0\,|P^{I}_{00}\,|0\,\rangle \sum_{\lambda}\langle I\,\lambda;2\;\;-\lambda\,|I{+}2\;0\,\rangle\, g_{\lambda}(I) \qquad (\mathrm{C}\cdot 9)\\
&= \langle I{+}2\;M;20\,|IM\,\rangle\,\langle 0\,|P^{I+2}_{00}\,|0\,\rangle \sum_{\lambda}\langle I{+}2\;\lambda\,;2\;\;-\lambda\,|I0\,\rangle\, g_{\lambda}(I+2). \qquad (\mathrm{C}\cdot 10)
\end{aligned}$$

From $(C\cdot 9) = (C\cdot 10)$, (4·15) can be analytically given.
